

NUMERICAL METHODS FOR TIME-CHANGED STOCHASTIC DIFFERENTIAL EQUATIONS DRIVEN BY ADDITIVE NOISE

AUTHOR A¹ AND AUTHOR B^{2,*}

ABSTRACT. This paper introduces a novel numerical approach specifically tailored for a class of highly nonlinear time-changed stochastic differential equations (SDE). The coefficients of these SDE meet the super-linear growth condition. By employing the Lamperti transformation, we convert the multiplicative noise present in these equations into additive noise, thereby simplifying the computation of numerical solutions and enhancing the order of convergence. The study not only investigates the strong convergence of the transformed SDEs but also provides a detailed analysis of the convergence order. Furthermore, numerical simulations are conducted to substantiate the theoretical findings, showcasing the method's significant advantage in improving the convergence order. This research offers a new perspective and tool for the numerical analysis of time-changed SDEs.

1. INTRODUCTION

In this paper, we investigate the rate of strong convergence of a numerical approximation scheme for an SDE of the form

$$dy(t) = a(y(t))dE(t) + b(y(t))dB(E(t)) \quad (1.1)$$

where the coefficients a and b satisfy some regularity conditions. However we are not concerned with these regular conditions, but more with the regular conditions of the SDE coefficients after the transformation of the Lamperti transform. Here, $E(t)$ represents the inverse subordinator process, and $B(t)$ represents the standard Brownian motion that is independent of $E(t)$, with the precise mathematical definition provided in Section 2.

2. PRELIMINARIES

In this paper, $(\Omega, \mathcal{F}, \mathbb{P})$ represents a complete probability space, and $D = (D_t)_{t \geq 0}$ denotes a subordinated process with Laplace exponent ψ , starting from 0, where the killing rate of ψ is 0 and it has a Lévy measure ν . That is, D is a one-dimensional, non-decreasing Lévy process starting at 0 with càdlàg paths, whose Laplace transform is:

$$\mathbb{E}[e^{-sD_t}] = e^{-t\psi(s)}, \quad \text{where} \quad \psi(s) = \int_0^\infty (1 - e^{-sy}) \nu(dy), \quad s > 0,$$

and $\int_0^\infty (y \wedge 1) \nu(dy) < \infty$. We consider the case where the Lévy measure ν is infinite, i.e., $\nu(0, \infty) = \infty$, meaning compound Poisson subordination is not considered. Let $E = (E(t))_{t \geq 0}$ be the inverse of D , i.e.:

$$E(t) := \inf\{u > 0; D_u > t\}, \quad t \geq 0.$$

We refer to E as the inverse subordinated process. If the subordinated process D is stable and its index is $\beta \in (0, 1)$, then $\psi(s) = s^\beta$, and E is called the inverse β -stable subordinated process. Assuming $\nu(0, \infty) = \infty$ implies that D has strictly increasing paths with infinitely many jumps, thus E has continuous, non-decreasing paths starting from 0. Moreover, the inverse relationship between D and E implies that for all $t, x \geq 0$, we have $\{E_t > x\} = \{D_x < t\}$. Note that jumps in D correspond to constant (random) time intervals in E , and during these constant periods, any time-changed process of the form $X \circ E = (X_{E_t})_{t \geq 0}$ also remains constant. If B is a standard Brownian motion independent of D , particles represented by the time-changed Brownian motion $B \circ E$ are considered trapped and immobile during constant periods; note that although $B \circ D$ is a Lévy process, $B \circ E$ is not even a Markov process. (See figure 2.1)

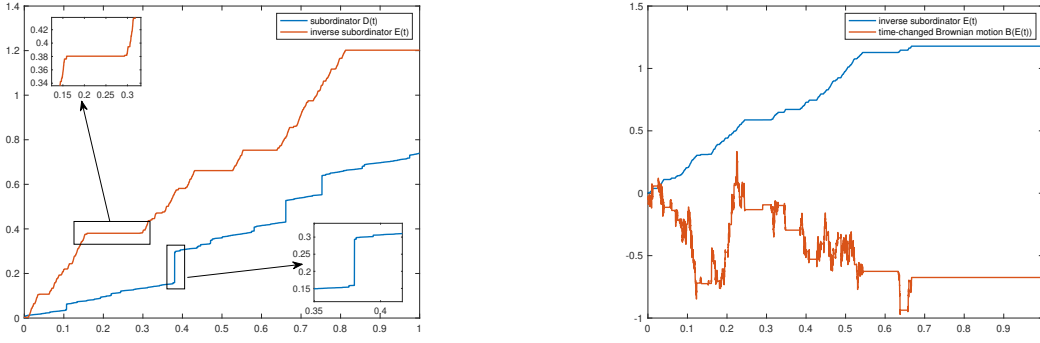

FIGURE 2.1. The left figure shows the subordinator D with stability index $\alpha = 0.8$ and the corresponding inverse subordinator E . The right figure shows the inverse subordinator E with stability index $\alpha = 0.8$ and the corresponding time-changed Brownian motion.

E and $B \circ E$ both start from 0. For the quadratic variation, we have

$$[B \circ E, B \circ E] = E \quad \text{and} \quad [E, E] = [B \circ E, E] = 0.$$

For more details on stochastic calculus for time-changed semimartingales, see Section 4 of [4].

Now, let's introduce the Lamperti transformation for time change. Let $S = (l, r)$, where $-\infty \leq l < r \leq \infty$, and let a and b be continuously differentiable functions from S to S . Consider the following SDE:

$$dy(t) = a(y(t))dE(t) + b(y(t))dB(E(t)) \quad (2.1)$$

and assume it has a unique strong solution in S , i.e.,

$$\mathbb{P}(y(t) \in S, t \geq 0) = 1.$$

If $b(x) > 0$ holds for all $x \in S$, then we can use the Lamperti transformation

$$F(x) = \lambda \int^x \frac{1}{b(y)} dy \quad (2.2)$$

for some $\lambda > 0$. Provided $F^{-1} : F(S) \rightarrow S$ is well-defined, let $x(t) = F(y(t))$. Using the time-change Itô formula from [8], we get:

$$dx(t) = f(x(t))dE(t) + \lambda dB(E(t)) \quad (2.3)$$

where

$$f(x) = \lambda \left(\frac{a(F^{-1}(x))}{b(F^{-1}(x))} - \frac{1}{2}b'(F^{-1}(x)) \right), \quad x \in F(S),$$

and $F(D) = (F(l), F(r))$. This transformation converts the nonlinear term of the diffusion into the drift term. In the subsequent part of this paper, we will focus on studying SDE (2.3) with additive noise.

Now, we describe an approximation method for the inverse subordinated process E given in [5] and [6]. Fix an equidistant step size $\delta > 0$ and a time interval $T > 0$. To approximate E over the interval $[0, T]$, we first simulate the sample path of the subordinated process D with independent and stationary increments, setting $D_0 = 0$, and then proceed with the rule $D_i^\delta := D_{i-1}^\delta + Z_i$, where $i = 1, 2, 3, \dots$, and $(Z_i)_{i \in \mathbb{N}}$ is an i.i.d. sequence with each Z_i following the distribution $Z = \Delta D_\delta$. We stop this process once we find an integer N such that $T \in [D_{N\delta}, D_{(N+1)\delta})$. Note that an \mathbb{N} -valued random variable N indeed exists because $D_t \rightarrow \infty$ as $t \rightarrow \infty$ almost surely. To generate the random variables (Z_i) , one can use the algorithm provided in Chapter 6 of [2]. Next, define $E^\delta := (\min(n \in \mathbb{N}; D_{n\delta} > t) - 1)\delta$. The process $E^\delta = (E_t^\delta)_{t \geq 0}$ is a non-decreasing step function with constant jump size δ , and the i -th waiting time is $Z_i = D_i^\delta - D_{i-1}^\delta$. Indeed, it is easy to see that for $n = 0, 1, 2, \dots, N$, when $t \in [D_{n\delta}, D_{(n+1)\delta})$, $E^\delta = n\delta$. Specifically, $E^\delta = N\delta$. As stated in [10,16], the process E^δ effectively approximates E ; that is, almost surely,

$$E_t - \delta \leq E^\delta \leq E_t \quad \text{for all } t \in [0, T].$$

Now, for $n = 0, 1, 2, \dots, N$, set

$$\tau_n = D_{n\delta}.$$

Assuming the independence between B and D , we can approximate the Brownian motion B over time steps $\{0, \delta, 2\delta, \dots, N\delta\}$. Based on this, define the discrete-time process $(X_{\tau_n})_{n \in \{0, 1, 2, \dots, N\}}$ as $X_0 := x_0$, and for $n = 0, 1, 2, \dots, N-1$, we have

$$X_{\tau_{n+1}} := X_{\tau_n} + f(X_{\tau_n})(E_{\tau_{n+1}} - E_{\tau_n}) + \sigma(B_{E_{\tau_{n+1}}} - B_{E_{\tau_n}}). \quad (2.4)$$

Due to the relationship $E_{\tau_n} = n\delta$, the above equation is equivalent to

$$X_{\tau_{n+1}} := X_{\tau_n} + f(X_{\tau_n})\delta + \sigma(B_{(n+1)\delta} - B_{n\delta}). \quad (2.5)$$

Note that although the expression (2.5) seems to take non-random time steps, in fact, we do take random time steps $\tau_0, \tau_1, \tau_2, \dots, \tau_N$ to discretize the driving process $E = (E_t)_{t \geq 0}$ and $B \circ E = (B_{E_t})_{t \geq 0}$, as shown in (2.4); thus, the key characteristic of the random trapping events in the time-change process (i.e., generating constant time intervals) is actually captured by the random step sizes $\tau_{n+1} - \tau_n = D_{(n+1)\delta} - D_{n\delta} = \Delta D_\delta$. Additionally, note that we do not discretize the SDE using non-random time steps; if we did, it would become very difficult because the driving processes E and $B \circ E$ do not have independent increments nor stationary increments.

To define a continuous-time process $(X_t^\delta)_{t \in [0, T]}$, we use continuous interpolation; that is, when $s \in [\tau_n, \tau_{n+1})$,

$$X_s := X_{\tau_n} + \int_{\tau_n}^s f(X_{\tau_n}) dE_r + \int_{\tau_n}^s \sigma dB_{E_r}. \quad (2.6)$$

Define

$$n_t = \max \{n \in \mathbb{N} \cup \{0\}; \tau_n \leq t\} \text{ for } t \geq 0.$$

Then it is clear that for any $t > 0$, we have $\tau_{n_t} \leq t < \tau_{n_t+1}$. Using (2.5) and the identity $X_s - x_0 = \sum_{i=0}^{n_s-1} (X_{\tau_{i+1}} - X_{\tau_i}) + (X_s - X_{\tau_{n_s}})$, we can express $X_s - x_0$ as

$$\sum_{i=0}^{n_s-1} [f(E_{\tau_i}, X_{\tau_i}) \delta + \sigma(B_{(i+1)\delta} - B_{i\delta})] + (X_s - X_{\tau_{n_s}}).$$

where we used $i\delta = E_{D_{i\delta}} = E_{\tau_i}$. Using (2.6) and the fact that $\tau_i = \tau_{n_r}$ for any $r \in [\tau_i, \tau_{i+1})$, we can rewrite the latter in a more tractable form:

$$X_s = x_0 + \int_0^s f(X_{\tau_{n_r}}) dE_r + \int_0^s \sigma dB_{E_r}. \quad (2.7)$$

Introducing the following three lemmas on time change from [8]:

Lemma 2.1 (First Variable Change Formula). *Let B be a one-dimensional standard Brownian motion. If $H \in L(B(t), \mathcal{F}_t)$, then $H_{E(t-)} \in L(B_{E(t)}, \mathcal{F}_{E(t)})$. Furthermore, for all $t \geq 0$, almost everywhere*

$$\int_0^{E_t} H_s dB(s) = \int_0^t H_{E(s-)} dB_{E(s)}.$$

Lemma 2.2 (Second Variable Change Formula). *Let B be a one-dimensional standard Brownian motion. Assume D and E satisfy $[D \rightarrow E]$ or $[D \leftarrow E]$. Assume B and E are synchronized. If $K \in L(B_{E(t)}, \mathcal{F}_{E(t)})$, then $(K_{D(t-)}) \in L(B(t), \mathcal{F}_{E(D_t)})$. Furthermore, for all $t \geq 0$, almost everywhere*

$$\int_0^t K_s dB_{E(s)} = \int_0^{E_t} K_{D(s-)} dB(s).$$

Lemma 2.3 (Itô Formula). *Let B be a one-dimensional standard Brownian motion. Let D and E satisfy $[D \rightarrow E]$ or $[D \leftarrow E]$. X is a stochastic process defined by the following SDE:*

$$X(t) := \int_0^t A(s) ds + \int_0^t F(s) dE(s) + \int_0^t G(s) dB(E(s))$$

where $A(s) \in L(t, \mathcal{F}_{E(t)})$, $F(s) \in L(E(t), \mathcal{F}_{E(t)})$, and $G(s) \in L(B(E(s)), \mathcal{F}_{E(t)})$. If $f \in C^2(\mathbb{R})$, then $f(X(t))$ is an $\mathcal{F}_{E(t)}$ -semimartingale, and for all $t \geq 0$, we have

$$\begin{aligned} f(X(t)) - f(0) &= \int_0^t f'(X(s)) A(s) ds + \int_0^{E(t)} f'(X(D(s-))) F(D(s-)) ds \\ &+ \int_0^{E(t)} f'(X(D(s-))) G(D(s-)) dB(s) + \frac{1}{2} \int_0^{E(t)} f''(X(D(s-))) \{G(D(s-))\}^2 ds. \end{aligned}$$

Next, introduce the discrete Gronwall inequality:

Lemma 2.4. *Let $\Delta t > 0, g_n, \lambda_n \in \mathbb{R}, \eta > 0, a_1 = 0$, and suppose $1 - \eta \Delta E_j > 0, 1 + \lambda_n > 0, n \in \mathbb{N}$. If*

$$a_{n+1} \leq a_n(1 + \lambda_n) + \eta a_{n+1} \Delta E_n + g_{n+1}$$

then the following inequality holds:

$$a_n \leq \sum_{j=0}^{n-1} \prod_{i=j}^n (1 - \eta \Delta E_i) g_{j+1} \prod_{l=j+1}^{n-1} (1 + \lambda_l) \quad (2.8)$$

The following lemma is crucial for proving the main theorems in this paper, quoting the lemma from [7].

Lemma 2.5. *Assume that in the Laplace transform of the inverse subordinated process $E(t)$, $\psi(s) = s^\alpha$. Then*

$$\lim_{t \rightarrow \infty} \frac{E_t}{t} = 0, \text{ a.s.} \quad (2.9)$$

Lemma 2.6. *If E is the inverse of the subordinated process D , and its Laplace exponent ψ has a regular variation index at infinity $\beta \in [0, 1)$. If $\beta = 0$, further assume $\nu(0, \infty) = \infty$. Fix $\lambda > 0$, $t > 0$, and $r > 0$.*

- (1) *If $r < \frac{1}{1-\beta}$, then $\mathbb{E}[e^{\lambda E_t^r}] < \infty$.*
- (2) *If $r > \frac{1}{1-\beta}$, then $\mathbb{E}[e^{\lambda E_t^r}] = \infty$.*

Lemma 2.7. *For any given $0 = t_0 < ih < t_1 < t_2 < \dots < t_n < (i+1)h$, we have:*

$$\mathbb{E} \left[\int_{ih}^{(i+1)h} \int_{ih}^{t_n} \dots \int_{ih}^{t_2} 1 dE(t_1) \dots dE(t_{n-1}) dE(t_n) \right] \leq Ch^{1+(n-1)\beta} \quad (2.10)$$

where C is a constant independent of h .

Proof. Now, introduce the random measure Π on $[0, \infty)$, defined as $\Pi((s, t]) = E(t) - E(s)$, where $t > s \geq 0$. Let $\{C(t)\}_{t \geq 0}$ be a Cox process driven by Π , i.e., conditional on $\Pi = \lambda$, the distribution of $\{C(t)\}$ is equivalent to that of an inhomogeneous Poisson process with intensity λ . Note that according to [3], $\{C(t)\}$ is a renewal process with the renewal function:

$$u(t) = \mathbb{E}[C(t)] = \mathbb{E}[E(t)] = \frac{t^\alpha}{\Gamma(\alpha + 1)} \quad (2.11)$$

For the renewal process $C(t)$, see [1], we obtain

$$\mathbb{E}[dC(t_n) \dots dC(t_1)] = \prod_{i=1}^n u'(t_i - t_{i-1}) dt_i$$

where $0 = t_0 < t_1 < t_2 < \dots < t_n$. Since the factorial moments of the Cox process $C(t)$ are equal to the ordinary moments of its driving measure Π , see [1], we get

$$\mathbb{E}[dE(t_n) \dots dE(t_1)] = \prod_{i=1}^n u'(t_i - t_{i-1}) dt_i.$$

Thus:

$$\begin{aligned} I &= \mathbb{E} \left[\int_{ih}^{(i+1)h} \int_{ih}^{t_n} \int_{ih}^{t_{n-1}} \dots \int_{ih}^{t_2} 1 dE(t_1) \dots dE(t_{n-2}) dE(t_{n-1}) dE(t_n) \right] \\ &= \int_{ih}^{(i+1)h} \int_{ih}^{t_n} \int_{ih}^{t_{n-1}} \dots \int_{ih}^{t_2} 1 \mathbb{E}[dE(t_1) \dots dE(t_{n-2}) dE(t_{n-1}) dE(t_n)] \\ &= \frac{\alpha^n}{\Gamma^n(\alpha + 1)} \int_{ih}^{(i+1)h} \int_{ih}^{t_n} \int_{ih}^{t_{n-1}} \dots \int_{ih}^{t_2} \prod_{i=1}^{i=n} (t_i - t_{i-1})^{\alpha-1} dt_1 \dots dt_{n-1} dt_n \end{aligned}$$

Next, consider the integral term separately:

$$I_1 = \int_{ih}^{t_2} (t_2 - t_1)^{\alpha-1} t_1^{\alpha-1} dt_1$$

Make the following transformation: let $t_1 = ih + s_1 h$ and $t_2 = ih + s_2 h$, where h is the step size, hence $s_1, s_2 \in [0, 1]$. Since we do not consider time at the origin, $i = \frac{T}{h}$ where T is a time range, thus

$$\begin{aligned} I_1 &= \int_0^{s_2} (s_2 - s_1)^{\alpha-1} h^{\alpha-1} (ih + s_1 h)^{\alpha-1} h ds_1 \\ &= h^\alpha \int_0^{s_2} (s_2 - s_1)^{\alpha-1} (ih + s_1 h)^{\alpha-1} ds_1 \end{aligned}$$

Since $(ih + s_1 h)^{\alpha-1}$ is monotonically decreasing with respect to s_1 in $[0, 1]$, and the integrand and integration range in I_n are positive, we have

$$\begin{aligned} I_1 &\leq h^\alpha \int_0^{s_2} (s_2 - s_1)^{\alpha-1} (ih)^{\alpha-1} ds_1 \\ &= T^{\alpha-1} h^\alpha \int_0^{s_2} (s_2 - s_1)^{\alpha-1} ds_1 \end{aligned}$$

Let $w_1 = s_2 - s_1$, thus

$$I_1 \leq T^{\alpha-1} h^\alpha \int_0^{s_2} (s_2 - s_1)^{\alpha-1} ds_1 = T^{\alpha-1} h^\alpha \int_0^{s_2} w_1^{\alpha-1} dw_1 = \frac{T^{\alpha-1} s_2^\alpha}{\alpha} h^\alpha$$

Therefore:

$$I \leq Ch^\alpha \int_{ih}^{(i+1)h} \int_{ih}^{t_n} \int_{ih}^{t_{n-1}} \dots \int_{ih}^{t_3} \prod_{i=3}^n (t_i - t_{i-1})^{\alpha-1} dt_2 \dots dt_{n-1} dt_n$$

Similarly, analyzing the following integral:

$$I_2 = \int_{ih}^{t_3} (t_3 - t_2)^{\alpha-1} dt_2 \leq Ch^\alpha$$

Therefore:

$$I \leq Ch^{2\alpha} \int_{ih}^{(i+1)h} \int_{ih}^{t_n} \int_{ih}^{t_{n-1}} \dots \int_{ih}^{t_4} \prod_{i=4}^n (t_i - t_{i-1})^{\alpha-1} dt_3 \dots dt_{n-1} dt_n$$

By iterating this process, we get:

$$I \leq Ch^{(n-1)\alpha} \int_{ih}^{(i+1)h} 1 dt_1 \leq Ch^{1+(n-1)\alpha}$$

□

3. MAIN RESULTS: THE STRONG CONVERGENCE OF EM METHOD

Assumption 3.1. In this section, we assume that the drift coefficient f of the SDE (2.3) satisfies the global Lipschitz condition, that is, there exists a constant $K > 0$ such that

$$|f(x) - f(y)| \leq K|x - y|. \quad (3.1)$$

Assumption 3.2. In this section, we assume that the drift coefficient f of the SDE (2.3) satisfies the linear growth condition, that is, there exists a constant $K > 0$ such that

$$|f(x)| \leq K(1 + |x|). \quad (3.2)$$

Assumption 3.3. *In this section, we assume that the drift coefficient f of the SDE (2.3) is twice continuously differentiable, and there exists a constant $K > 0$ such that*

$$|f(x)f'(x)| + |\sigma f'(x)| + |\sigma^2 f''(x)| \leq K(1 + |x|). \quad (3.3)$$

The following proposition aims to derive sufficient conditions for the existence of the p -th moment of $\sup_{0 \leq r \leq T} |X_r|$, where X is the solution to the SDE (2.3). These conditions are necessary for establishing the main theorems of this paper.

Proposition 3.1. *Let X be the solution to the SDE (2.3), where f satisfies assumption 3.1 and assumption 3.2. Then for any $p \geq 1$, there exist constants c_1, c_2 such that $\mathbb{E}_B[Y_T^{(p)}] < c_1 e^{c_2 E_T}$, where $Y_t^{(p)} := 1 + \sup_{0 \leq r \leq t} |X_r|^p$.*

Proof. Let $S_\ell := \inf\{t \geq 0 : Y_t^{(p)} > \ell\}$ for $\ell \in \mathbb{N}$. Since the solution X has continuous paths and $Y_t^{(p)} < \infty$ for each $t \geq 0$, $S_\ell \uparrow \infty$ as $\ell \rightarrow \infty$. For \mathbb{P}_D almost every path, we first apply the Gronwall-type inequality to the function $t \mapsto \mathbb{E}_B[Y_{t \wedge S_\ell}^{(p)}]$ for a fixed ℓ , then let $t = T$ and let $\ell \rightarrow \infty$ in the resulting inequality to establish the upper bound for $\mathbb{E}_B[Y_T^{(p)}]$. Note that by the definition of S_ℓ ,

$$\int_0^t \mathbb{E}_B[Y_{r \wedge S_\ell}^{(p)}] dE_r \leq \ell E_t < \infty,$$

which allows us to safely apply the Gronwall-type inequality.

Suppose $p \geq 2$, as the result for $1 \leq p < 2$ follows directly by applying the result for $p \geq 2$ and Jensen's inequality. By the time-changed Itô formula, we have $X_s^p = x_0^p + J_s + K_s$, where

$$J_s := \int_0^s \sigma p X_r^{p-1} dB_{E_r};$$

$$K_s := \int_0^s \left\{ p X_r^{p-1} f(X_r) + \frac{\sigma^2}{2} p(p-1) X_r^{p-2} \right\} dE_r.$$

Fix $t \in [0, T]$ and $\ell \in \mathbb{N}$. By assumption 3.2 and the inequality $(x + y + z)^p \leq c_p(x^p + y^p + z^p)$, where $x, y, z \geq 0$ and $c_p = 3^{p-1}$, we have

$$\mathbb{E}_B \left[\sup_{0 \leq s \leq t \wedge S_\ell} |K_s| \right] \leq \left(pc_p K + \frac{1}{2} p(p-1) c_p K^2 \right) \int_0^{t \wedge S_\ell} \mathbb{E}_B[Y_r^{(p)}] dE_r.$$

Since $(J_s)_{s \geq 0}$ is a local martingale, applying the BDG inequality gives

$$\mathbb{E}_B \left[\sup_{0 \leq s \leq t \wedge S_\ell} |J_s| \right] \leq b_1 \mathbb{E}_B \left[\left(\int_0^{t \wedge S_\ell} \sigma^2 p^2 X_r^{2p-2} dE_r \right)^{1/2} \right],$$

thus,

$$\begin{aligned} \mathbb{E}_B \left[\sup_{0 \leq s \leq t \wedge S_\ell} |J_s| \right] &\leq b_1 \mathbb{E}_B \left[pc_p K \left(Y_{t \wedge S_\ell}^{(p)} \int_0^{t \wedge S_\ell} Y_r^{(p)} dE_r \right)^{1/2} \right] \\ &\leq \frac{1}{2} \mathbb{E}_B \left[Y_{t \wedge S_\ell}^{(p)} \right] + 2b_1^2 p^2 c_p^2 K^2 \int_0^{t \wedge S_\ell} \mathbb{E}_B \left[Y_r^{(p)} \right] dE_r, \end{aligned}$$

where the last inequality follows from the basic inequality $(ab)^{1/2} \leq a/\lambda + \lambda b$ for any $a, b, \lambda > 0$, with $\lambda := 2b_1 pc_p K$. Note that for any non-negative process $(L_t)_{t \geq 0}$,

$$\int_0^{t \wedge S_\ell} L_r dE_r \leq \int_0^t L_{r \wedge S_\ell} dE_r.$$

Indeed, the inequality is obvious if $t \leq S_\ell$, while if $t > S_\ell$,

$$\int_0^{S_\ell} L_r dE_r + \int_{S_\ell}^t L_{S_\ell} dE_r \geq \int_0^{t \wedge S_\ell} L_r dE_r.$$

Thus, from the above estimates for J_s and K_s , we have

$$\mathbb{E}_B[Y_{t \wedge S_\ell}^{(p)}] \leq 2(1 + |x_0|^p) + 2K^2 (pc_p K + (p(p-1)c_p/2 + 2b_1^2 p^2 c_p^2)) \int_0^t \mathbb{E}_B[Y_{r \wedge S_\ell}^{(p)}] dE_r.$$

Applying the Gronwall-type inequality, we get

$$\mathbb{E}_B[Y_{t \wedge S_\ell}^{(p)}] \leq 2(1 + |x_0|^p) e^{2K^2 E_T (pc_p K + (p(p-1)c_p/2 + 2b_1^2 p^2 c_p^2))}.$$

Letting $t = T$ and letting $\ell \rightarrow \infty$, since $\xi(u)$ is independent of ℓ , and by applying the monotone convergence theorem, we obtain

$$\mathbb{E}_B[Y_T^{(p)}] \leq 2(1 + |x_0|^p) e^{2K^2 E_T (pc_p K + (p(p-1)c_p/2 + 2b_1^2 p^2 c_p^2))}. \quad (3.4)$$

□

Next, we prove the first important theorem.

Theorem 3.1. *Let X be the solution to the SDE (2.3), under the conditions of assumption 3.1, assumption 3.2, and assumption 3.3. Let X_t be the EM numerical method defined in (2.5) and (2.6). Then there exists a constant $C > 0$ independent of δ , such that for all $\delta \in (0, 1)$,*

$$\mathbb{E} \left[\sup_{0 \leq s \leq T} |X(s) - X_t| \right] \leq C\delta.$$

Hence, X_t converges strongly to $X(t)$ uniformly with order 1 on $[0, T]$.

Proof. using the Itô formula expansion, we obtain

$$X_{\tau_{n+1}} = X_{\tau_n} + \int_{\tau_n}^{\tau_{n+1}} f(X_{\tau_n}) dE_r + \int_{\tau_n}^{\tau_{n+1}} \sigma dB_{E_r} + R_{(\tau_n, \tau_{n+1})}; \quad (3.5)$$

$$R_{(a,b)} := \int_a^b \int_a^s \left(f(X_{\tau_{n_r}}) f'(X_{\tau_{n_r}}) + \frac{\sigma^2}{2} f''(X_{\tau_{n_r}}) \right) dE_r dE_s + \int_a^b \int_a^s \sigma f'(X_{\tau_{n_r}}) dB_{E_r} dE_s, \quad (3.6)$$

Subtracting (3.5) from (2.6), we get

$$Z_t := \sup_{0 \leq s \leq t} |X_s - X_s^\delta| \leq I_1 + I_2,$$

where

$$I_1 := \sup_{0 \leq s \leq t} \left| \int_0^s f(X_{\tau_{n_r}}) - f(X_{\tau_{n_r}}^\delta) dE_r \right|;$$

$$I_2 := \sup_{0 \leq s \leq t} \left| \sum_{i=0}^{n_s-1} R_{(\tau_i, \tau_{i+1})} + R_{(\tau_{n_s}, s)} \right|.$$

For I_1 , from assumption 3.1, we get

$$\mathbb{E}_B[I_1] \leq K \int_0^t \mathbb{E}_B[Z_r] dE_r. \quad (3.7)$$

The main technical part involves the remainder term I_2 , which consists of two different double integrals: $dE_{r_1} dE_{r_2}$ and $dB_{E_{r_1}} dE_{r_2}$. We will handle these integrals separately below.

For the first integral $dE_{r_1} dE_{r_2}$,

$$\begin{aligned} & \mathbb{E}_B \left[\sup_{0 \leq s \leq t} \left| \int_0^s \int_{\tau_{n_2}}^{r_2} f f' + \frac{\sigma^2}{2} f'' dE_{r_1} dE_{r_2} \right| \right] \\ & \leq \frac{3}{2} K \mathbb{E}_B[Y_T^{(1)}] \int_0^t \int_{\tau_{n_{r_2}}}^{r_2} dE_{r_1} dE_{r_2} \\ & \leq \frac{3}{2} K E_T \mathbb{E}_B[Y_T^{(1)}] \delta. \end{aligned} \quad (3.8)$$

The appearance of δ instead of δ^α is primarily due to our use of a randomly discretized numerical scheme.

On the other hand, we need to estimate $\mathbb{E}_B[\sup_{0 \leq s \leq t} |M_{n_s} + U_s|]$, where $M_0 := 0$, and for $n \geq 1$, $M_n := \sum_{i=0}^{n-1} L_i$,

$$L_i := \int_{\tau_i}^{\tau_{i+1}} \int_{\tau_i}^{r_2} \sigma f' dB_{E_{r_1}} dE_{r_2}, \quad U_s := \int_{\tau_{n_s}}^s \int_{\tau_{n_s}}^{r_2} \sigma f' dB_{E_{r_1}} dE_{r_2}.$$

This expression, along with the proofs of Lemmas 5.7.1 and 10.8.1 in reference [12], shows that the discrete-time process $(M_n)_{n \geq 0}$ is a square-integrable $((\mathcal{F}_{n\delta})_{n \geq 0}, \mathbb{P}_B)$ -martingale with initial value 0. Thus, by the BDG inequality (3.2) and the independence of L_i ,

$$\mathbb{E}_B \left[\sup_{0 \leq s \leq t} M_{n_s}^2 \right] \leq b_2 \sum_{i=0}^{n_t-1} \mathbb{E}_B[L_i^2].$$

Therefore, by the Cauchy-Schwarz inequality,

$$\begin{aligned} \mathbb{E}_B \left[\sup_{0 \leq s \leq t} M_{n_s}^2 \right] & \leq b_2 \delta \sum_{i=0}^{n_t-1} \int_{\tau_i}^{\tau_{i+1}} \mathbb{E}_B \left[\int_{\tau_i}^{r_2} |\sigma f'|^2 dE_{r_1} \right] dE_{r_2} \\ & \leq 2b_2 \delta K^2 \mathbb{E}_B[Y_T^{(2)}] \sum_{i=0}^{n_t-1} \int_{\tau_i}^{\tau_{i+1}} (E_{r_2} - E_{\tau_i}) dE_{r_2} \\ & \leq 2b_2 E_T K^2 \mathbb{E}_B[Y_T^{(2)}] \delta^2. \end{aligned} \quad (3.9)$$

On the other hand,

$$\begin{aligned} \mathbb{E}_B \left[\sup_{0 \leq s \leq t} U_s^2 \right] & \leq \mathbb{E}_B \left[\sup_{0 \leq s \leq t} (E_s - E_{\tau_{n_s}}) \int_{\tau_{n_s}}^s \left| \int_{\tau_{n_s}}^{r_2} \sigma f' dB_{E_{r_1}} \right|^2 dE_{r_2} \right] \\ & \leq \delta \int_0^t \mathbb{E}_B \left[\sup_{s \in [r_2, t]} \left| \int_{\tau_{n_s}}^{r_2} \sigma f' dB_{E_{r_1}} \right|^2 \right] dE_{r_2}. \end{aligned} \quad (3.10)$$

Since $\{(\tau_{n_s}, r_2) : r_2 \leq s \leq t\} \subset \{(\tau_{n_{r_2}}, u) : \tau_{n_{r_2}} \leq u \leq r_2\}$,

$$\mathbb{E}_B \left[\sup_{s \in [r_2, t]} \left| \int_{\tau_x}^{r_2} \sigma f' dB_{E_{r_1}} \right|^2 \right]$$

$$\begin{aligned}
&\leq \mathbb{E}_B \left[\sup_{u \in [\tau_{n_{r_2}}, r_2]} \left| \int_{\tau_{n_{r_2}}}^u \sigma f' dB_{E_{r_1}} \right|^2 \right] \\
&\leq b_2 \mathbb{E}_B \left[\int_{\tau_{n_{r_2}}}^{r_2} |\sigma f'|^2 dE_{r_1} \right] \\
&\leq 2b_2 K^2 \mathbb{E}_B[Y_T^{(2)}] \delta.
\end{aligned}$$

Therefore, the upper bound for (3.10) is $2b_2 E_T K^2 \mathbb{E}_B[Y_T^{(2)}] \delta^2$. Combining this with (3.9):

$$\mathbb{E}_B \left[\sup_{0 \leq s \leq t} |M_{n_s} + U_s|^2 \right] \leq 8b_2 E_T K^2 \mathbb{E}_B[Y_T^{(2)}] \delta^2. \quad (3.11)$$

From the estimates (3.8) and (3.11),

$$\mathbb{E}_B[I_2] \leq \left\{ \frac{3}{2} E_T \mathbb{E}_B[Y_T^{(1)}] + (8b_2 E_T \mathbb{E}_B[Y_T^{(2)}])^{1/2} \right\} K \delta. \quad (3.12)$$

Now, combining (3.7) and (3.12) with $\mathbb{E}_B[Y_T^{(1)}] \leq \sqrt{2} \mathbb{E}_B[Y_T^{(2)}]^{1/2}$:

$$\mathbb{E}_B[Z_t] \leq \xi_2(E_T) \mathbb{E}_B[Y_T^{(2)}]^{1/2} \delta + K \int_0^t \mathbb{E}_B[Z_r] dE_r.$$

where $\xi_2(u) := K(\frac{3\sqrt{2}}{2}u + (8b_2u)^{1/2})$. Applying the Gronwall-type inequality, taking \mathbb{E}_D on both sides and using the Cauchy-Schwarz inequality:

$$\mathbb{E}[Z_T] \leq \mathbb{E}[\xi_2^4(E_T)]^{1/4} \mathbb{E}[(Y_T^{(2)})^2]^{1/4} \mathbb{E}[e^{2KE_T}]^{1/2} \delta.$$

Since $\mathbb{E}[e^{\lambda E_t}] < \infty$ and $\mathbb{E}[E^n(t)] < \infty$ for any $\lambda > 0, t > 0, n > 0$, and combining this with proposition 3.1, the theorem holds. \square

4. MAIN RESULTS: THE STRONG CONVERGENCE OF BEM METHOD

Assumption 4.1. *In this section, we assume that the drift coefficient f of the SDE (2.3) satisfies the super-linear growth condition, that is, there exists a constant $K > 0$ and $\gamma > 1$ such that*

$$|f(x)| \leq K(1 + |x|^\gamma). \quad (4.1)$$

Assumption 4.2. *In this section, we assume that the drift coefficient f of the SDE (2.3) is twice continuously differentiable, and there exists a constant $K > 0$ and $\gamma > 1$ such that*

$$|f(x)f'(x)| + |\sigma f'(x)| + |\sigma^2 f''(x)| \leq K(1 + |x|^\gamma). \quad (4.2)$$

Assumption 4.3. *In this section, we assume that the drift coefficient f of the SDE (2.3) satisfies the one-sided Lipschitz condition, that is, there exists a constant $K > 0$ such that*

$$(x - y)(f(x) - f(y)) \leq K|x - y|^2. \quad (4.3)$$

For the existence and uniqueness proof of the solution to the SDE (2.3) under the condition of the drift coefficient f being monotone, refer to the proof in [8] for the case where the drift satisfies the global Lipschitz condition. Similar to (2.5) and (2.6), we can derive the corresponding BEM numerical scheme.

$$X_{\tau_{n+1}} := X_{\tau_n} + f(X_{\tau_{n+1}}) \delta + \sigma (B_{(n+1)\delta} - B_{n\delta}). \quad (4.4)$$

$$X_s := X_{\tau_n} + \int_{\tau_n}^s f(X_{\tau_{n+1}}) dE_r + \int_{\tau_n}^s \sigma dB_{E_r}. \quad (4.5)$$

Similar to proposition 3.1, we can derive the following proposition.

Proposition 4.1. *Let X be the solution to the SDE (2.3), where f satisfies ?? and assumption 4.1. Then for any $p \geq 1$, there exist constants c_1, c_2 such that $\mathbb{E}_B[Y_T^{(p)}] < c_1 e^{c_2 E_T}$, where $Y_t^{(p)} := 1 + \sup_{0 \leq r \leq t} |X_r|^p$.*

Next, we prove the second important theorem.

Theorem 4.1. *Let X be the solution to the SDE (2.3), under the conditions of assumption 4.1, assumption 4.2, and assumption 4.3. Let X_t be the BEM numerical method defined in (4.4) and (4.5). Then there exists a constant $C > 0$ independent of δ , such that for all $\delta \in (0, 1)$,*

$$\mathbb{E} \left[\sup_{0 \leq s \leq T} |X(s) - X_t| \right] \leq C\delta.$$

Hence, X_t converges strongly to $X(t)$ uniformly with order 1 on $[0, T]$.

5. NUMERICAL SIMULATIONS

Example 1 (Time-Changed OU Process). Consider the time-changed Ornstein-Uhlenbeck process driven by Brownian motion

$$dX(t) = \mu X(t) dE_t + \sigma dB_{E_t}. \quad (5.1)$$

For assumption 3.1, assumption 3.2, and assumption 3.3, it is clear that this example satisfies these conditions. The corresponding EM numerical scheme for this equation is:

$$X_{i+1} = (1 + \mu \Delta E_i) X_i + \sigma \Delta B_{E_i}.$$

In our numerical experiments, we focus on the L_1 error at the endpoint $T = 1$, so we define

$$e_T^i = \mathbb{E} \left| X_T^{\delta_i} - X_T^{\delta_i} \right|,$$

where $X_T^{\delta_i}$ is the simulated value at T with step size δ_i , $\delta_i = 2^{-i}$. For our numerical experiments, we set $\mu = 1$ and $\sigma = 1$, and use the Monte Carlo method:

$$e_T^i \approx \frac{1}{10^3} \sum_{j=1}^{10^3} \left| X_T^{\delta_{14}} - X_T^{\delta_i} \right|, \quad \text{where } i = 6, 7, 8, 9.$$

We use the step size 2^{-14} as a reference and estimate the L_1 error using step sizes $2^{-6}, 2^{-7}, 2^{-8}, 2^{-9}$. The table below compares the convergence rates and errors for different α values.

α	0.3000	0.4000	0.5000	0.6000	0.7000	0.8000	0.9000	1.0000
Convergence Order	0.9937	1.0345	1.0195	1.0204	1.0261	1.0318	1.0283	1.0281

TABLE 5.1. Convergence rates and errors for different α values

Example 2. Consider the time-changed CIR process driven by Brownian motion

$$dy(t) = \kappa(\theta - y(t))dE(t) + \sigma\sqrt{y(t)}dB(E(t)), \quad t \geq 0, \quad y(0) > 0. \quad (5.2)$$

If $2\kappa\theta \geq \sigma^2$, then $D = (0, \infty)$ and ?? holds in $(\alpha, \beta) = (0, \infty)$. Moreover, using the Itô formula with $X(t) = F(y(t))$, where F is defined by (2.2), we can obtain the Lamperti transformation of the time-changed CIR process:

$$dX(t) = f(X(t))dE(t) + \frac{1}{2}\sigma dB(E(t)), \quad t \geq 0, \quad X(0) = \sqrt{y(0)}. \quad (5.3)$$

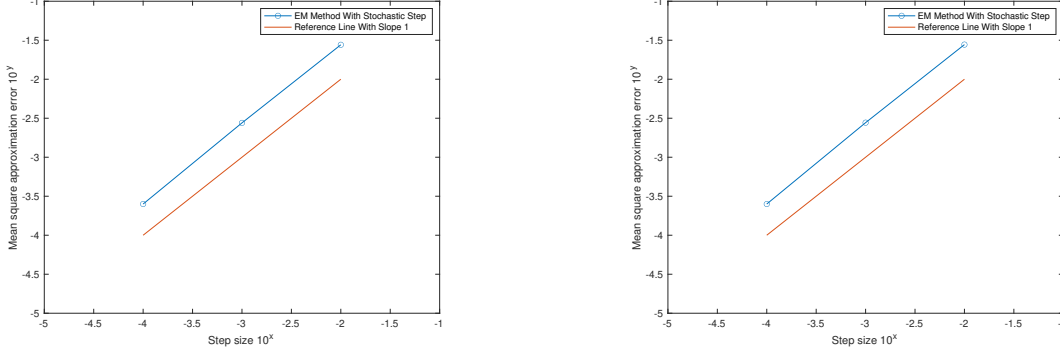

FIGURE 5.1. L_1 error of the EM method with stochastic steps. The left figure shows $\alpha = 0.4$ and the right figure shows $\alpha = 0.8$.

where

$$f(X) = \frac{1}{2}\kappa(\theta_v X^{-1} - X), \quad X > 0 \quad (5.4)$$

with $\theta_v = \theta - \frac{\sigma^2}{4\kappa}$. The BEM numerical scheme is as follows:

$$X_{t_{i+1}} = X_{t_i} + f(X_{t_{i+1}})\Delta E_i + \frac{1}{2}\sigma\Delta B_{E_i}, \quad k = 0, 1, \dots \quad (5.5)$$

We observe that

$$f'(X) = -\frac{1}{2}\kappa(\theta_v X^{-2} + 1) \quad (5.6)$$

and

$$f(X)f'(X) + \frac{\sigma^2}{2}f''(X) = -\frac{\kappa^2}{4}(\theta_v^2 X^{-3} - X) + \frac{1}{2}\kappa\theta_v X^{-3}\sigma^2. \quad (5.7)$$

Therefore, to satisfy ??, it is sufficient to have

$$\sup_{0 \leq t \leq T} \mathbb{E}[X(t)^{-3}] = \sup_{0 \leq t \leq T} \mathbb{E}[y(t)^{-\frac{3}{2}}] < \infty. \quad (5.8)$$

For the bounded moments of the time-changed CIR process $y(t)$, we have

$$\sup_{0 \leq t \leq T} \mathbb{E}[y(t)^q] < \infty \quad \text{for } q > -\frac{2k\theta}{\sigma^2}. \quad (5.9)$$

Next, we verify the bounded moments for the exact solution of the time-changed CIR process (5.2).

Proposition 5.1. *For the time-changed CIR process driven by Brownian motion (5.2) with $y_0 > 0$ and $1 < p < \frac{2K\theta}{\sigma^2} - 1$, there exists a constant C such that*

$$\sup_{t \in [0, T]} \mathbb{E} \left[(y(t))^{-p} \right] \leq C(1 + y(0)^{-p}).$$

Proof. Define the stopping time $\tau_n = \inf\{0 < s \leq T; y(s) \leq 1/n\}$. By applying the Itô formula, we obtain

$$\begin{aligned} \mathbb{E}_B [(y(t \wedge \tau_n))^{-p}] &= y(0)^{-p} - p \mathbb{E}_B \left[\int_0^{t \wedge \tau_n} \frac{K(\theta - y(s))}{(y(s))^{p+1}} dE(s) \right] \\ &\quad + p(p+1) \frac{\sigma^2}{2} \mathbb{E}_B \left[\int_0^{t \wedge \tau_n} \frac{1}{(y(s))^{p+1}} dE(s) \right] \\ &\leq y(0)^{-p} + pK \int_0^t \mathbb{E}_B \left(\frac{1}{(y(s \wedge \tau_n))^p} \right) dE(s) \\ &\quad + \mathbb{E}_B \left[\int_0^{t \wedge \tau_n} \frac{p \left(\frac{(p+1)\sigma^2}{2} - K\theta \right)}{(y(s))^{p+1}} dE(s) \right]. \end{aligned}$$

We can find a positive constant \underline{C} such that when $\frac{(p+1)\sigma^2}{2} - K\theta < 0$, for any $y(0) = x > 0$, we have

$$\frac{p \left(\frac{(p+1)\sigma^2}{2} - K\theta \right)}{x^{p+1}} \leq \underline{C}.$$

Therefore,

$$\mathbb{E}_B [(y(t \wedge \tau_n))^{-p}] \leq y(0)^{-p} + \underline{C}E(T) + pK \int_0^t \sup_{r \in [0, s]} \mathbb{E}_B [(y(r \wedge \tau_n))^{-p}] dE(s).$$

Using the Gronwall inequality, we obtain

$$\sup_{t \in [0, T]} \mathbb{E}_B [(y(t \wedge \tau_n))^{-p}] \leq (y(0)^{-p} + \underline{C}E(T)) \exp(pKE(T)).$$

Taking \mathbb{E}_D on both sides and using the Cauchy-Schwarz inequality, we get

$$\begin{aligned} \sup_{t \in [0, T]} \mathbb{E} [(y(t \wedge \tau_n))^{-p}] &\leq \mathbb{E} [(y(0)^{-p} + \underline{C}E(T)) \exp(pKE(T))] \\ &\leq \sqrt{\mathbb{E} [(y(0)^{-p} + \underline{C}E(T))^2] \mathbb{E} [\exp(2pKE(T))]} \end{aligned}$$

From [2], we have

$$\mathbb{E}[E^n(t)] = \frac{n!}{\Gamma(n\alpha + 1)} t^{n\alpha}, \quad (5.10)$$

$$\mathbb{E}[e^{\lambda E(t)}] < \infty, \quad (5.11)$$

where $\lambda \in \mathbb{R}, t > 0$. Finally, letting $n \rightarrow +\infty$, we complete the proof. \square

Remark 5.1. Here, we have only proved the existence of moments for $1 < p < \frac{2K\theta}{\sigma^2} - 1$. Actually, it can be proven that $p < \frac{2K\theta}{\sigma^2}$, but the proof is too complicated and not necessary for our results.

For ??, it can be verified that it is sufficient to ensure that $1 < \frac{4}{3} \frac{\kappa\theta}{\sigma^2}$ holds. This interval is covered by $1 < p < \frac{2K\theta}{\sigma^2} - 1$, so it suffices to ensure that p is within this range. As for ??, it can be easily verified that there exists such a κ in $(0, \infty)$ to satisfy this condition. Therefore, from ??, it follows that for the time-changed CIR process, the strong convergence order of the BEM numerical scheme is α .

Example 3. Consider the time-changed CEV process driven by Brownian motion

$$dy(t) = \kappa(\theta - y(t))dE(t) + \sigma y(t)^\alpha dB_{E(t)}. \quad (5.12)$$

Here, $0.5 < \alpha < 1, \kappa, \theta, \sigma > 0$. By transforming $X(t) = F(y(t))$ where F is defined in (2.2), we get that ?? holds in $(\alpha, \beta) = (0, \infty)$, and we have

$$dX(t) = f(X(t))dE(t) + (1 - \alpha)\sigma dB(E(t)),$$

where

$$f(X) = (1 - \alpha) \left(\kappa \theta X^{-\frac{\alpha}{1-\alpha}} - \kappa X - \frac{\alpha \sigma^2}{2} X^{-1} \right), \quad X > 0.$$

We also need to verify ??. Since $\alpha > 0.5$, we have $\frac{1}{1-\alpha} > 2$, so

$$f'(X) = -\alpha \kappa \theta X^{-\frac{1}{1-\alpha}} - (1 - \alpha)\kappa + (1 - \alpha)\frac{\alpha \sigma^2}{2} X^{-2}, \quad X > 0,$$

and

$$f''(X) = \frac{\alpha}{1 - \alpha} \kappa \theta X^{-\frac{2-\alpha}{1-\alpha}} - (1 - \alpha)\alpha \sigma^2 X^{-3}.$$

The following proposition verifies the bounded moments for the exact solution of the time-changed CEV process (5.12).

Proposition 5.2. *For the time-changed CEV process (5.12) driven by Brownian motion, with $X_0 > 0$, for any $\frac{1}{2} < \alpha < 1$ and any $p > 0$, there exists a constant C such that*

$$\sup_{t \in [0, T]} \mathbb{E} \left[(y(t))^{-p} \right] \leq C(1 + y(0)^{-p}).$$

Proof. Define the stopping time $\tau_n = \inf\{0 < s \leq T; y(s) \leq 1/n\}$. Using the Itô formula, we get

$$\begin{aligned} \mathbb{E}_B \left[(y(t \wedge \tau_n))^{-p} \right] &= y(0)^{-p} - p \mathbb{E}_B \left[\int_0^{t \wedge \tau_n} \frac{\kappa(\theta - y(s))}{(y(s))^{p+1}} dE(s) \right] \\ &\quad + p(p+1) \frac{\sigma^2}{2} \mathbb{E}_B \left[\int_0^{t \wedge \tau_n} \frac{1}{(y(s))^{p+2(1-\alpha)}} dE(s) \right] \\ &\leq y(0)^{-p} + p\kappa \int_0^t \mathbb{E}_B \left(\frac{1}{(y(s \wedge \tau_n))^p} \right) dE(s) \\ &\quad + \mathbb{E}_B \left[\int_0^{t \wedge \tau_n} \left(p(p+1) \frac{\sigma^2}{2} \frac{1}{(y(s))^{p+2(1-\alpha)}} - p \frac{\kappa \theta}{(y(s))^{p+1}} \right) dE(s) \right] \end{aligned}$$

We can find a positive constant C such that, for any $y(0) = x > 0$,

$$\left(p(p+1) \frac{\sigma^2}{2} \frac{1}{x^{p+2(1-\alpha)}} - p \frac{\kappa \theta}{x^{p+1}} \right) \leq C.$$

From the calculations, we get that $\underline{C} = p(2\alpha - 1) \frac{\sigma^2}{2} \left[(p + 2(1 - \alpha)) \frac{\sigma^2}{2\kappa\theta} \right]^{\frac{p+2(1-\alpha)}{2\alpha-1}}$ is the smallest upper bound. Therefore,

$$\mathbb{E}_B \left[(y(t \wedge \tau_n))^{-p} \right] \leq y(0)^{-p} + \underline{C} E(T) + p\kappa \int_0^t \sup_{r \in [0, s]} \mathbb{E}_B \left[(y(r \wedge \tau_n))^{-p} \right] dE(s).$$

Applying the Gronwall inequality, we get

$$\sup_{t \in [0, T]} \mathbb{E}_B \left[(y(t \wedge \tau_n))^x \right] \leq (y(0)^{-p} + \underline{C} E(T)) \exp(p\kappa E(T)).$$

Taking the expectation \mathbb{E}_D on both sides and using the Cauchy-Schwarz inequality, we get

$$\begin{aligned} \sup_{t \in [0, T]} \mathbb{E} \left[(y(t \wedge \tau_n))^x \right] &\leq \mathbb{E} \left[(y(0)^{-p} + \underline{C} E(T)) \exp(p\kappa E(T)) \right] \\ &\leq \sqrt{\mathbb{E} \left[(y(0)^{-p} + \underline{C} E(T))^2 \right] \mathbb{E} [\exp(2p\kappa E(T))]} \end{aligned}$$

From [2], we have

$$\mathbb{E}[E^n(t)] = \frac{n!}{\Gamma(n\alpha + 1)} t^{n\alpha} \quad (5.13)$$

$$\mathbb{E}[e^{\lambda E(t)}] < \infty \quad (5.14)$$

where $\lambda \in \mathbb{R}, t > 0$. Finally, letting $n \rightarrow +\infty$, we complete the proof. \square

From the Lamperti transformation, we know that the inverse moments of $X(t)$ can be controlled by the inverse moments of $y(t)$, so ?? is satisfied. Therefore, according to ??, we conclude that the convergence order of the BEM numerical scheme for the time-changed CEV process driven by Brownian motion is α .

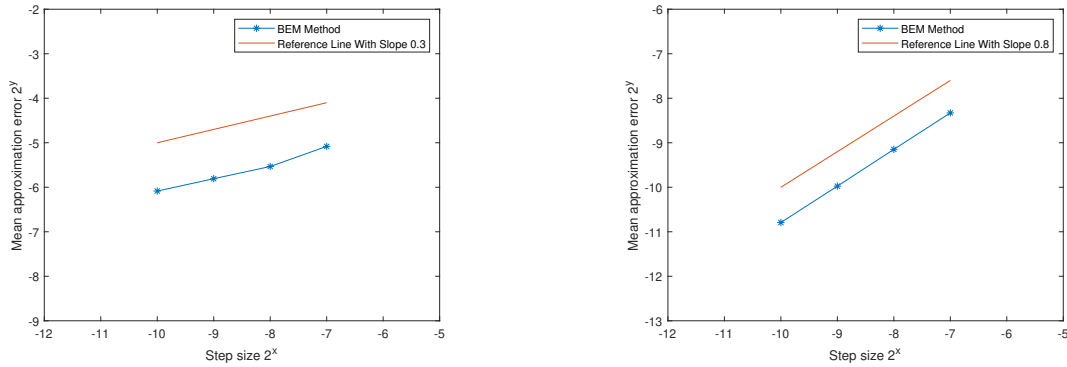

FIGURE 5.2. Absolute error estimation between the numerical solution and the analytical solution of the time-changed CIR process. The left figure shows $\alpha = 0.3$, and the right figure shows $\alpha = 0.8$.
